# 1. Static Loads

- a. Anchor bolt preload
- b. Compressor deadweight
- c. Limits of compressive loads on grout material and concrete

## Static Loads

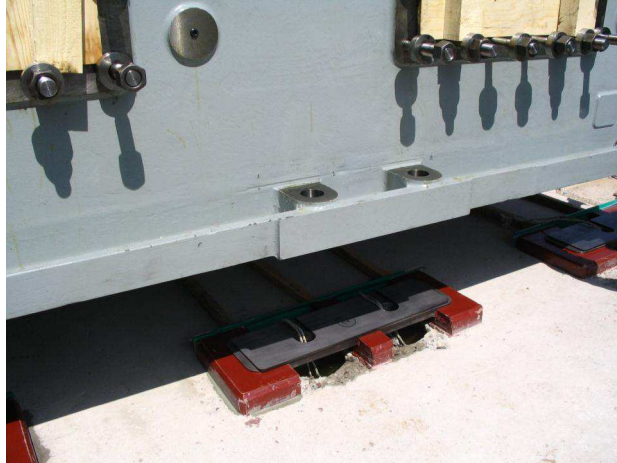

### Anchor bolt preload required for

- Generating friction between frame and foundation
- Limiting the fatigue stress in the bolts
- Limitation of frame vibrations

# Static Loads

- Compressor deadweight

# Static loads;

- Limits

Epoxy compressive strength and creep is very temperature dependent (oil sump temperature!!)

Epoxy chocks design pressure maximum 7.0 MPa.  
(Marine industry 3.5 MPa, sometimes approval for 5MPa)

# Static loads

- Limits

Concrete compressive strength minimum 28 MPa (API 618 5<sup>th</sup> edition refers to the API RP 686).

## 2. Anchor bolt type and selection

a. Summary of bolt types with advantages & disadvantages

**b. Anchor bolt termination point**

The simplest design would be a nut termination and calculations have been performed for both nut and plate termination.

## Anchor bolt termination point

Source GMRC report TR-97-2

## Termination requirements

- A termination having a diameter of 3 times the bolt diameter or more meets the bearing load requirements
- GMRC SWRI Report No. TR 97-6 a termination plate diameter of three to four bolt diameters
- GMRC: the recommended termination thickness is 1.35 to 1.5 times the bolt diameter.

## 3. Friction, edge and spacing

- a. Friction between footings and soleplates
- b. Friction between footings/ soleplates and grout/concrete
- c. Edge distance and bolt spacing

## Friction, edge and spacing

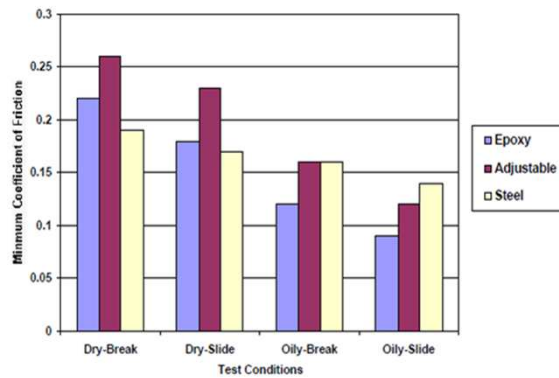

Figure 2-56. Minimum Friction Coefficient for Cast-Iron on Various Other Materials, from GMRC Technical Report TR97-3 [2]

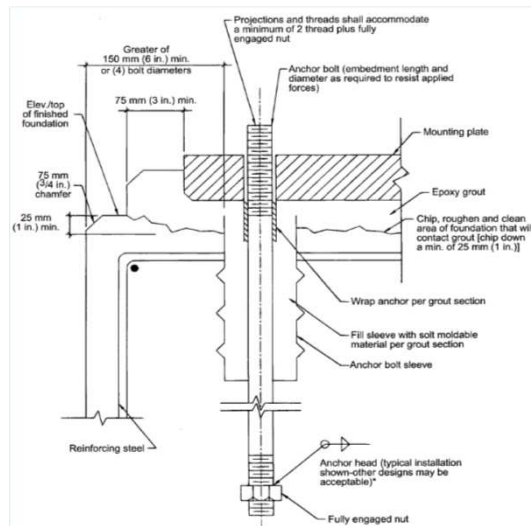

## Friction, edge and spacing

- Friction, based on clamping force and deadweight must be sufficient to restrain the Free Forces and Moments.
- Bolt design and load to meet a safety factor of 2 on the friction force

## Friction, **edge and spacing**

- API 686 2nd edition

- Pre-installed or post-installed**
- Thread and nut (design and lubrication)
- Tightening
- Bolt material and preload
- Anchor bolt length: free, embedment
- Bolt pockets (size and bond strength)

## Thread and nut (design and lubrication)

- At least 2½ threads above the fully engaged nuts (API RP 686).
- Threads and nut bearing faces adequately oiled/greased (no molykote etc)

# Bolt material and preload

Materials	standard	Grade 8.8	A193 B7
Minimum specified Yield strength (Mpa)	300	640	724

## Bolt preload

is defined as a % of the minimum specified yield strength

Factors to be considered:

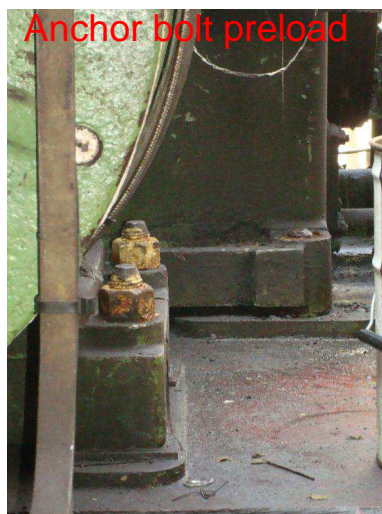

- Calculations are based on the tensile stress only.
- The applied tools determine the total stress (torque, shear and tensile)
- The fatigue stress range is determined by the prestress.
- The local stresses in concrete chocks and plates
- Bolt sizes.
- Stress intensification and corrosion.

The suggested allowable preload is between 50 and 70% YS

Higher strength materials than B7 should not be used

# Bolt material

Low % yield strenght:

- Moderate stress level
- Design margin
- Less susceptible to corrosion and over torque

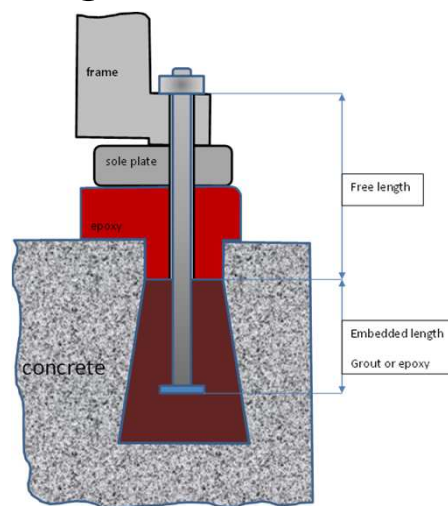

## Tightening (torque-tension)

- calibrated manual torque wrench or hydraulic torque wrench
- hydraulic jack or the use of special nuts (preferred)
  - no torsional load on and torsional deformation of the anchor bolt during tightening

## Length: free, embedment

## Bolt pockets (size and bond strength)

Pocket size and depth must be large enough to accommodate the tension and the shear force.

# Effect of thermal expansion

## summary

- Anchorbolts to be designed to obtain a firm contact load on the foundation under all operational conditions
- Enough friction is required to stop the horizontal vibration
- Maintain sufficient edge distances
- The embedded and free length must be large enough to either ensure good long term integrity and to have sufficient elasticity for the horizontal thermal expansion
- Maximum compressive load on epoxy and concrete to be taken into account
- Do not use very high tensile strength steels to avoid stress corrosion effects
- Larger bolts and high strength steel bolt preferably tensioned by hydraulic jacks or special nuts
- Grout supplier instructions must be followed, eg. mixing quantities and mixing speed, temperature, layer thickness, time etc
